

Briefing to Seattle City Council's Civil Rights, Utilities, Economic Development and Arts Committee

April 23, 2019

History of Invasives Species Program and Knotweed

• SPU enacts Secondary Use Policies, which prohibits use of herbicides in Cedar River Municipal Watershed.

• Staff finds knotweed and begins control efforts by covering and digging.

• SPU initiates Invasive Species Program in watershed (funded as CIP).

Botanist surveys find multiple additional knotweed patches. SPU continues treating by covering. Mechanical treatment concluded to be ineffective.

• City Council passes ordinance allowing SPU to treat knotweed with herbicide (imazapyr) in watershed.

• Council passes three consecutive 3-year ordinances to allow use of imazapyr in watershed. Imazapyr treatment leads to significant decline in knotweed.

• SPU pursuing renewed ordinance authority to continue treating knotweed at maintenance levels in the watershed.

2009

2010-

2019

Knotweed Program Success

- Knotweed coverage has declined by approximately 95 percent since 2011.
- Herbicide use has decreased annually from 2011 (678 oz.) to 2018 (10 oz.).
- SPU estimates annual use of 16 oz. imazapyr on 28 acres to continue control.

Ecological Reasons to Control Knotweed

- Causes erosion.
- Impacts water quality.
- Limits species diversity.
- Reduces habitat complexity.
- Spreads rapidly.

Civic Reasons to Control Knotweed

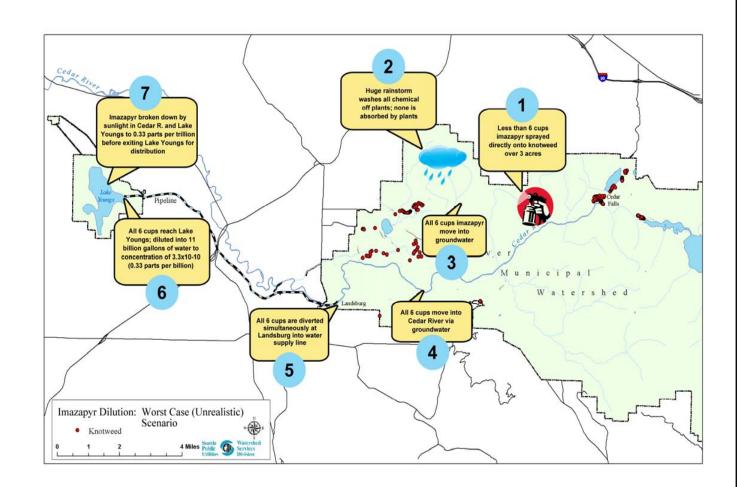

- King County legally requires control of knotweed on Cedar River and tributaries.
- Downstream partners rely on knotweed being treated in municipal watershed.
- Knotweed necessitates systematic removal.

Imazapyr and Human Health

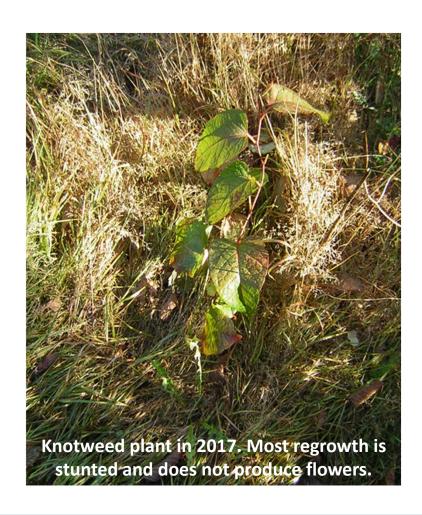

- Imazapyr inhibits enzymes found only in plants, so it has very low animal toxicity.
- WSU toxicologist prepared a worst-case scenario for herbicide application in the watershed.
- The toxicologist found the worst-case scenario concentration was 60,000,000 (0.33 ppb) times lower than the NOAEL* for a human child.
- * No observable adverse effect level

Imazapyr and Pollinators

- SPU avoids spraying if pollinators are present on a plant.
- SPU uses methods consistent with the King County Noxious Weed Control Program.
- SPU currently treats plants that are primarily small regrowth and have no flowers.

Imazapyr vs. Glyphosate

- Glyphosate is being elevated to Tier I pesticide by City of Seattle.
- Imazapyr is already Tier I, as are most herbicides used by the City; Tier I precautions are already in place.
- Animals are more sensitive to glyphosate than imazapyr.
- Imazapyr provides more effective treatment over time, leading to less herbicide usage.

Environmental Protection

- SPU collects water quality samples before and after applications and found limited imazapyr detections since 2011.
- SPU developed new water quality protocol in 2018, took more samples with no detections.
- SPU protects pollinators by avoiding spraying during flowering periods.
- SPU protects applicators by following proper Tier I herbicide protocol.

Persistence is Key to Success

- There are still areas of knotweed in the watershed needing continued maintenance.
- An estimated 16 ounces of imazapyr per year will be needed to maintain control of the population.
- The goal is eradication of knotweed from the Cedar River Watershed.
